## 39 1 Introduction

40 This document should be read along side of TAS3 architecture documents. It is  
41 a requirement that *secure* architecture addresses all known threats. Therefore this  
42 document effectively specifies security related requirements (other more business  
43 oriented requirements are discussed in other documents) for the architecture.

44 Once architecture documents stabilize, the intent is to reference here the spe-  
45 cific parts that solve these threats.

46 Our goal is to answer all threats specified in [NIST-SP800-30]. For program-  
47 mers [Meier09] provides a good check list and [Meier08] a short list for those in  
48 a hurry. Further threats in [?] are addressed as well.

## 49 2 Threat Analysis

50 This section addresses Reqs. *D1.2-2.7-Safe* and *D1.2-2.8-Avail*. Also Req. *D1.2-*  
51 *2.9-Correct* is touched from secure programming perspective.

### 52 2.1 Other work

- 53 • [SAML2security]
- 54 • [IDWSFSecPriv]
- 55 • [NIST-SP800-30]
- 56 • [Meier09] provides a check list and [Meier08] a short list

### 57 2.2 Business threats

58 **T21-IDTheft** Identity Theft

59 **T22-Illegal** Illegal transactions

### 60 2.3 Trust model threats

61 **T31-OverPrivil** Over-privileged process and service accounts.

62 **T32-UnTTP** Untrustworthy Third Party.

63 **2.4 Architectural threats**

64 **T41-BPMflaw** Business process modelling flaws. How to audit or validate the  
65 model?

66 **T42-BPMdel** Accidental deletion of process steps such as authorization or vali-  
67 dation

68 **T43-Berserk** Dynamically adaptive business process gone wild

69 **2.5 Trust misconfiguration threats**

70 **T51-TNins** Insertion of illegitimate members in trust network.

71 **T52-Mole** Moles in trust network. A previously trusted member turns into  
72 rogue. How to detect? How to rectify?

73 **T55-PolluteRep** Pollution of reputation of other party

74 **T56-Augment** Illicit augmentation of reputation by party itself

75 **T57-Deface** Defacing Front End web site can cause damage to reputation of the  
76 Front End. Defacing attacks can happen through same means as phishing  
77 (T111-Phish) and also through break-ins, either through network, or physi-  
78 cal.

79 **T58-WrongCAs** Insertion of wrong CAs into a trust network

80 **T59-WrongAAs** Wrongly assigning source of authority to an attribute authority

81 **T510-WrongLOA** Wrong assertion of LOA value by an IDP

82 **2.6 Protocol misconfiguration threats**

83 **T61-Replay** Replay attack. See CR211-Uniq.

84 **T62-UnEncLink** Unencrypted links e.g. SSLnull cipher suites.

85 **T63-UnAnLink** Unauthenticated links

86 **2.7 Authorization misconfiguration threats**

87 **T71-WrongGrant** Returning grant instead of deny leading to unauthorised ac-  
88 cess

89 **T72-WrongDeny** Returning deny instead of grant leaving to DOS.

90 **T73-WrongObs** Returning wrong obligations

91 **T74-MissingObs** Missing obligations from authz decisions

92 **T75-OKAC** Attribution of wrong access rights to an otherwise trusted member

93 **2.8 Ontology threats**

94 **T81-SameButDiff** Same term meaning different things to two parties leads to  
95 illicit access, due to wrong rule inadvertently matching.

96 **2.9 Exposure threats**

97 **T91-Eavesdrop** Exposure of data due to network sniffing or eavesdropping.  
98 Counter measure: encrypt data and manage keys right.

99 **T91-DBLeak** Exposure of data due to database files or transaction logs. Counter  
100 measure: encrypt data and manage keys right.

101 **T92-TamperNet** Modification of data in transit. Counter measuers: signing or  
102 verification of a hash over the data.

103 **T93-TamperDB** Modification of data in database.

104 **T94-ExptLeak** Error condition or exception reveals too much data or system de-  
105 tails (usually to aid debugging). Exception output that appears in user in-  
106 terface or over the network is especially damning. Leakage to logs is also a  
107 threat.

108 **T95-CoreLeak** Error condition or exception causes a core dump that reveals too  
109 much data or system details (usually to aid debugging).

110 **2.10 Privacy threats**

111 **T101-LeakBackup** Eavesdropping on backups (see CR213-Backup)

112 **T102-Correlation** Database correlation by colluding entities (solution: do not  
113 leak correlation handles, i.e. use pseudonyms - see Architecture, Core Se-  
114 curity Architecture, Access Credentials, Pull Model)

115 **T103-TAIdP** IdP collects traffic analysis (and then sells or illicitly use it). Some  
116 counter measures:

- 117 • TN wide data retention policy, audit this: add compliance requirement
- 118 • Pure play IdP operator vs. mixed functions
- 119 • Centralized IdP well managed may be a good idea

120 **T104-TADI** Disco collects traffic analysis (and then sells or illicitly use it)

121 **T105-TA3rd** Traffic Analysis by Third Party

122 **T106-CorrAudit** Correlation handles of audit trail will also become correlation  
123 handles.

124 **T107-LogTokLeak** If WSC parties keeps log of User's pseudonym along with  
125 encrypted form of User's identifier at WSP, then WSC and WSP can corre-  
126 late and collude using the encrypted form. However this threat is acute only  
127 between directly interacting parties. In a chain of web services calls longer  
128 than 3, the nonneighboring parties are not in position to collude using this  
129 attack.

130 Current solution is to forbid logging the tokens, see CR53-DontLogTok.

131 **T108-PhishPII** Tricking user to reveal PII through phishing attack that poses a  
132 real looking web page to solicit PII. See also access version of the threat:  
133 T111-Phish.

134 **T109-SocEngPII** Social Engineering, talking users to revealing PII. See also ac-  
135 cess version of the threat: T112-SocEng.

136 **T1010-SnoopPII** Network eavesdropping to record PII.

137 **T1011-KbdLogPII** Keyboard logger or other malware to record credentials.

138 **T1012-MalwarePII** PII theft, e.g. copy private contact book, using malware.

139 **T1013-PIITheft** Physical theft of PII.

140 **2.11 Authentication threats**

141 **T111-Phish** Tricking user to reveal his authentication credentials through phishing  
142 attack that poses a real looking web page to solicit user's access credentials.  
143 This could be created through

- 144 a. DNS manipulation
- 145 b. Cross site scripting
- 146 c. Inappropriate insertion of content in legitimate site
- 147 d. Containment of legitimate site in illegitimate frame

148 See also PII version of threat: T108-PhishPII.

149 **T112-SocEng** Social Engineering, talking users to revealing access credentials.  
150 See also PII version of threat: T109-SocEngPII.

151 **T113-SnoopCred** Network eavesdropping to record credentials.

152 **T114-KbdLog** Keyboard logger or other malware to record credentials.

153 **T115-Malware** Credential theft, e.g. copy private key, using malware.

154 **T116-Theft** Physical credential theft.

155 **T117-Dict** Dictionary attack on password

156 **T118-Brute** Brute force attacks of simply trying out all credentials.

157 **T119-Cookie** Cookie replay attack. Use previously recorded cookie in context  
158 where authentication did not happen. Also arises if expired session cookie  
159 is allowed as a factor in authentication, resulting stronger factor not being  
160 demanded.

161 **T1110-Lure** Luring users to do stupid things like

- 162 a. Visit web sites that phish or contain malware
- 163 b. Install malware and troians
- 164 c. Voluntarily give out credentials or PII

165 **2.12 Impersonation threats**

166 **T121-Gift** Users giving away their credentials to others

167 **T122-Loss** Users losing their credentials

168 **T123-Careless** Users not protecting their credentials properly e.g. posting pass-  
169 words on post-it stickers

170 **T124-Delegation** Authentication delegation models in which  
171 the delegate assumes the user's original ID in-  
172 stead of using their own (e.g. as in Shibboleth see  
173 <https://spaces.internet2.edu/display/ShibuPortal/Solution+Proposal>)

174 **2.13 Repudiation threats**

175 **T131-Repud** Repudiation of events by any party (system entity or user).

176 **2.14 Unauditability threats**

177 **T141-AltSig** Alteration of signed message (see CR27-Sig and CR28-Vfy)

178 **T142-Tamper** Alteration of audit trail (see CR212-Trail)

179 **T143-LeakLogs** Eavesdropping on logs (see CR212-Trail)

180 **T144-NoAud** Insufficient auditing in the first place

181 **2.15 Software bug threats**

182 **T151-Overflow** Buffer overflow attack, to gain injection and execution of code,  
183 usually leading to compromise of the machine. Also heap overflow.

184 **T152-Inject SQL Query Injection** attack, causing database engine to execute  
185 unauthorized database statements. This threat also covers similar attacks  
186 on other databases or downstream services like shell scripts (command in-  
187 jection).

188 **T153-NI** Access control, signature verification, or other security feature not im-  
189 plemented. Testing only positive cases can easily ignore this type of threat.  
190 It is imperative that the test suites also include negative testing.

191 **T154-Input** Input MUST at all times be validated to conform to the expected  
192 syntax, and input in general should never be trusted unless there is a crypto-  
193 graphical or structural guarantee of trustworthiness. Some particular perils

- 194 a. Explicit inputs
- 195 b. Environment variables
- 196 c. URL and query string
- 197 d. CGI form fields
- 198 e. Cookies
- 199 f. HTTP headers
- 200 g. SOAP headers
- 201 h. Processing contexts of all sorts passed between software modules
- 202 i. Fields of certificates (from untrusted source, but you would not know  
203 until you manipulated the certificate to find out if it is trusted).
- 204 j. Metadata
- 205 k. Messages from event bus
- 206 l. Data coming from database (even if database is supposed to be trusted,  
207 it may have been compromised, thus checking for proper format will  
208 help to detect the breach and contain it).
- 209 m. Deserialization of any data. This is particularly acute when using eval  
210 to deserialize JSON data.

211 *Perl(1)* tainted feature provides a way to track untrusted user input. All  
212 untrusted input MUST be scrutinized for attack vectors, such as directory  
213 climbing (".." or " " = home directory) as a path component. Where relative  
214 path is expected, an absolute path - one starting by "/" - MUST NOT be  
215 allowed. All *shell(1)* or SQL escape characters (see also T152-Inject) are of  
216 highest suspicion until proven to be secure.

217 When validating input, preferred strategy is to test if input is good and any-  
218 thing that does not pass is bad. The alternative strategy of looking for known  
219 bad things (like ".." in path) is much weaker and prone to errors.

220 **T155-Mem** Code MUST NOT

- 221 a. Dereference a Null Pointer
- 222 b. Use Freed Memory

223

c. Doubly Free Memory

224

**T156-Fmt** Format string mismatch. In *printf(3)* format string it is easy to get the format specifiers and actual arguments mixed, resulting inappropriate format specifier being used for a given piece of data.

225

226

227

**T157-Trunc** Truncation of value. Sometimes truncated value can have different meaning.

228

229

**T158-Signed** Signed conversion of a value that may not have been identified.

230

231

232

233

234

235

236

237

**T159-CliValid** Reliance on client side validation is no good for server as an alternate client will not perform the validation. Server **MUST** at all times perform all security critical validations. Client side validation has value in (i) improving user experience and feedback, (ii) reducing network traffic by not submitting obviously invalid inputs, (iii) protecting client side processing like AJAX applications. Such applications **MUST** be suspicious of what is sent to them by server, in particular if they use JSON and plan to use *eval()* for processing it.

238

**T1510-XSiteScript** Cross Site Scripting.

239

240

**T1511-Stack** Stack overflow. Similar to T151-Overflow, but specifically applied to the argument and call stack of most compiled programs.

241

242

**T1512-HTML** Using non-validated input in the HTML output stream. This could lead into insertion of JavaScript on the generated page.

243

**T1513-PtrSub** Improper Pointer Subtraction

244

**T1514-EqEq** Assignment (=) instead of comparison (==).

245

## 2.16 Cloud threats

246

247

248

249

**T161-Panopticon** The cloud operator may gain excessive knowledge about the operation of the network as a whole, or even individual users, if too many Trust Network components and Service Providers are colocated with the same cloud operator.

250

251

**T162-Corr** The Cloud operator may be able to see data of several Service Providers and correlate this data.

252

253

**T163-CorrAud** The Cloud operator may be able to see all of the audit data and correlate it.

254 **2.17 Service Availability Threats**

255 **T161-DoS** Denial of Service by massive network load.

256 **T162-DNS** Poisoning DNS or taking DNS down will prevent legitimate players  
257 from communicating with each other.

258 **T163-Expt** Using program flaw or exception to trigger excessive resource con-  
259 sumption (spinning process, writing all logs full, and leaking memory) or  
260 to cause a service to crash.

261 **T164-GC** Feeding service request pattern (e.g. monotonically increasing in-  
262 put size so that previously freed memory is never enough to satisfy the  
263 new request) that causes fragmentation of memory, excessive or ineffective  
264 garbage collects, or memory leaks.

265 **3 Conclusion**

266 **4 Future work**

- 267 • SPOFs and fat targets: discovery, idmapper, IdP

## 304 Revision History

- 305 **03** 30.11.2008 Sampo
- 306 • Added some cloud threats
- 307 **02** 12.4.2009 Sampo
- 308 • Integrated into deliverable
  - 309 • Added references to SAML and IDWSF security analyses
- 310 **01** 11.3.2009 Sampo (sampo@symlabs.com)
- 311 • First draft out of blue
